Expander2 as a Prover and Rewriter

Peter Padawitz
TU Dortmund, Germany

January 26, 2019

Abstract

Expander2 is a flexible multi-purpose workbench for interactive term rewriting, graph transformation, theorem proving, constraint solving, flow graph analysis and other procedures that build up proofs or other rewrite sequences. Moreover, tailor-made interpreters display terms as two-dimensional structures ranging from trees and rooted graphs to a variety of pictorial representations that include tables, matrices, alignments, partitions, fractals and various tree-like or rectangular graph layouts.

An Expander specification consists of a signature with functions, predicates, axioms, theorems and conjectures (terms to be rewritten or formulas to be solved or proved). It describes a set of algebraic (constructor-based) and/or coalgebraic (destructor-based) types (formerly called swinging types). Syntactically, it follows Haskell (for presenting functions) and usual mathematical notations (for presenting relations and propositional, predicate-logic, modal and temporal operators). Predicates are interpreted as the least or greatest solutions of their Horn clause or co-Horn clause axioms, respectively.

The user interacts with the system at three levels of control over proofs and computations. At the top level, rules like Noetherian induction and incremental fixpoint co/induction are applied locally and step by step. At the medium level, goals are co/resolved or narrowed, i.e., axioms are applied exhaustively and iteratively. At the bottom level, built-in rules (some of them executing Haskell programs) simplify, i.e., (partially) evaluate terms and formulas, and thus hide routine steps of a proof or computation. Simplifications may be executed automatically after each step performed at the top or medium level. As the co/Horn axioms co/resolved or narrowed upon are part of the user-defined specification, so additional simplification rules (equations or equivalences) may be entered into the specification. Recently, functional and logical fixpoint operators have been integrated the simplifier along with corresponding (non-incremental) co/induction rules. Proofs and other rewrite sequences are automatically translated into proof terms that can be evaluated and modified later. Of course, a textual record listing all elements of the sequence and the rules producing them is also generated.

This paper presents an overview of Expander2 with particular emphasis on the system’s prover and rewriter capabilities.

1 Introduction

The following design goals distinguish Expander2 from many other proof editors or tools using formal methods:

- **Expander2** provides several representations of formal expressions and allows the user to switch between linear, tree-like and pictorial ones when executing a proof or computation on formulas or terms.
- Proof and computation steps take place at three levels of interaction: the simplifier automates routine steps, axiom-triggered computations are performed by narrowing and rewriting, analytical rules like induction and coinduction are applied locally and stepwise.
- The underlying logic is general enough to cover a wide range of applications and to admit the easy integration of special structures or methods by adding or exchanging signatures, axioms, theorems or inference rules including built-in simplifications.
- **Expander2** has an intelligent GUI that interprets user entries in dependence of the current values of certain global variables. This frees the user from entering input that can be deduced from the context in which the system actually works.

Proofs and computations performed with the system are correct with respect to the semantics of swinging types [17, 18, 19]. A swinging type is a functional-logic specification consisting of a many-sorted signature and a set of (generalized) Horn or co-Horn axioms (see section 3) that define relation symbols as least or greatest fixpoints and function symbols in accordance with the initial resp. final model induced by the specification.

Sortedness is only implicit because otherwise the proof and computation processes would become unnecessarily complicated. If used as a specification environment, the main purpose of Expander2 is proof editing and not type checking. Therefore, the syntax of signatures is kept as minimal as possible. The only
explicit distinction between different types is the one between constants on the one hand and functions and relations on the other hand, expressed by the distinction between first-order variables (fovars) and higher-order variables (hovars). Proofs or computations that depend on a finer sort distinction can always be performed by introducing and using suitable membership predicates.

The prover features of Expander2 do not aim at the complete automation of proof processes. Instead, they support natural derivations, which humans can comprehend and thus control easily. Natural deduction avoids skolemization and other extensive normalizations that make formulas unreadable and thus inappropriate for interactive proving. For instance, the simplifier (see Section 5), which turns formulas into equivalent "simplified" ones, prefers implication to negation.

Of course, many conjectures can be proved both comprehensibly and efficiently without any human intervention into the proof process. Such proofs often follow particular schemas and thus may be candidates for derived inference rules. However, proofs of program correctness usually do not fall into this category, especially if induction or coinduction is involved and the original conjecture must be generalized in a particular way.

In fact, the simplifier of Expander2 performs certain normalizations. But they are in compliance with natural deduction and deviate from classical normalizations insofar as, for instance, implications and quantifiers are not eliminated by introducing negations and new signature symbols, respectively. On the contrary, the simplifier eliminates negation symbols by moving them to literal positions and then are removed completely by transforming negated (co)predicates into their complements. Axioms for relations and their complements can be constructed from each other: If \( P \) is a predicate specified by Horn axioms, then these axioms can be transformed systematically into co-Horn axioms for the copredicate not\( P \), and vice versa. This follows from the fact that relation symbols are interpreted by the least resp. greatest solutions of their axioms provided that these are negation-free and thus induce monotonic consequence operators [17, 18].

Expander2 has been written in O’Haskell [12], an extension of Haskell [8] with object-oriented features for reactive programming and a typed interface to Tcl/Tk for developing GUIs. Besides providing a comfortable GUI the overall design goals of Expander2 were to integrate testing, proving and visualizing deductive methods, to admit several degrees of interaction and to keep the system open for extensions or adaptations of individual components to changing demands.

2 System components

![Diagram of System Components](image)

Figure 1. Components of Expander2
The main components of Expander2 are two copies of a **solver**, a **painter**, a **simplifier** an **enumerator** and a **recorder** that saves proofs and other computation sequences as well as executable proof terms. As Fig. 1 indicates, the components work together via several interfaces. For instance, the painter is used for drawing normal forms or solutions produced by the solver.

**Figure 2. The solver window**

The **solver** is accessed via a window for editing and displaying a list of trees that represents a disjunction or conjunction of logical formulas or a sum of algebraic terms (see Fig. ??). By moving the slider below the canvas of the solver window one selects the summand/factor to be shown on the canvas. If the parse text resp. parse tree button is pushed, the linear representation of a term or formula in the solver’s text field is translated into an equivalent tree representation on the canvas and vice versa. Both representations are editable. As a linear representation is edited by selecting substrings, the tree representation is edited by selecting subtrees or nodes or redirecting edges.

The **painter** consists of several widget interpreters from which one is selected and applied to the current trees or parts of them. The resulting pictorial representations are displayed in a painter window. Pictures can be edited in the painter window and completed to **widget graphs**. Widgets are built up of path, polygon and turtle action constructors that admit the definition of a variety of pictorial representations ranging from tables and matrices via string alignments, piles and partitions to complex fractals generated by **turtle systems** [25]. The latter define pictures in terms of sequence of basic actions that a turtle would perform when it draws the picture while moving over the canvas of a window. The turtle works recursively in two ways: it maintains a stack of positions and orientations where it may return to, and it may create trees whose pictorial representations are displayed at its current position.

The solver and its associated painter are fully synchronized: the selection of a tree in the solver window is automatically followed by a selection of the tree’s pictorial representation in the painter window and vice versa. Hence rewriting, narrowing and simplification steps can be carried out from either window.

The **enumerator** provides algorithms that enumerate trees or graphs and pass their results both to the solver and the painter. Currently, two algorithms are available: a generator of all sequence alignments [5, 22] satisfying constraints that are partly given by axioms, and a generator of all nested partitions of a list with a given length and satisfying constraints given by particular predicates. The painter displays an alignment in the way DNA sequences are usually visualized. A nested partition is displayed as a rectangular dissection of a square where different levels are colored differently.

The user of Expander2 operates on specifications (consisting of signatures and axioms), theorems, substitutions, trees (representing algebraic terms, logical formulas or transition systems to be evaluated, solved, proved, or executed, respectively) via commands selected from the solver’s menus (see Fig. ??). Sliders control the layout of a tree. With the slider in the middle of a solver window, one browses among several trees. All these actions yield input for the solver and may modify its **state variables**. Hence the solver can be regarded as a finite automaton whose actions are triggered not only by user input, but also by the actual system state. Here are the main state variables:

- The current **signature** consists of symbols denoting basic specifications consisting of signatures, axioms, theorems and/or conjectures, predicates interpreted as the least solutions of their (Horn) axioms, copredicates interpreted as the greatest solutions of their (co-Horn) axioms, constructors for
building up data, defined functions specified by (Horn) axioms or implemented as Haskell functions called by the simplifier, first-order variables that may be instantiated by terms or formulas, and higher-order variables that may be instantiated by functions or relations. Most built-in signature symbols have the same syntax and semantics as synonymous Haskell functions (see [22]).

- The current axioms and theorems are applied to conjectures and build up the top or medium level steps of a computation or proof. Axioms and theorems are applied by narrowing or rewriting. Narrowing/rewriting steps start with unifying/matching a subtree (the redex) with/against an axiom. Narrowing applies (guarded) Horn or co-Horn clauses, rewriting applies only unconditional, but possibly guarded equations. The guard of an axiom is a subformula to be solved before the axiom is applied.

- The current proof term represents the current proof as an executable expression for the purpose of later proof checking. It is build up automatically in parallel to the construction of a derivation and can be saved to a user-defined file. A saved proof term is loaded by writing its name into the entry field and pushing check proof term from file. This action overwrites the current proof term. Starting out from the current tree, the proof represented by the loaded proof term is carried out stepwise by pushing the → button. Each click triggers a proof step and the proof term is entered into the text field with the constant POINTER preceding the command that will be executed next. If the entry field contains a positive natural number n, n proof steps are performed sequentially and only the final proof state is displayed. By pushing the ← button one goes backwards. If the stop button is pushed, Expander2 leaves the proof check mode, i.e. the not-yet-evaluated part of the proof term is removed and all buttons regain their original function. Whenever the contents of the text field is parsed and thus turned into a new list of current trees, the proof term is initialized with commands that set the current values of all state variables that control the proof.

- The current substitution maps the variables of its domain to terms over the current signature. It is generated, modified and applied by particular commands.

- treeMode indicates whether the list trees of current trees (or other rooted graphs) is a singleton or represents a disjunction or conjunction of formulas or a sum (= disjoint union) of terms. True, False and () are the respective zero elements. The slider between the canvas and the text field of a solver window allows one to browse among the current trees and to select the one to be displayed on the canvas.

- The list treeposs consists of the positions of selected subtrees of the actually displayed tree. Subtrees are selected (and moved) by pushing the left mouse button while placing the cursor over their roots.

- varCounter maps a variable x to the maximal index i such that x occurs in the current proof. varCounter is updated when new variables are needed.

Expander2 allows the user to control proofs and computations at three levels of interaction. At the top level, analytic and synthetic inference rules and other syntactic transformations are applied individually and locally to selected subtrees. The rules cover single axiom applications, substitution or unification steps, Noetherian, Hoare, subgoal or fixpoint induction and coinduction. Derivations are correct if, in the case of trees representing terms, their sum is equivalent to the sum of their successors or, in the case of trees representing formulas, their disjunction/conjunction is implied by the disjunction/conjunction of their successors. The underlying models are determined by built-in data types and the least/greatest interpretation of Horn/co-Horn axioms. Incorrect deduction steps are recognized and cause a warning. All proper tree transformations are recorded, be they correct proofs or other transformations.

At the medium level, rewriting and narrowing realize the iterated and exhaustive application of all axioms for the defined functions, predicates and copredicates of the current signature. Rewriting terminates with normal forms, i.e. terms consisting of constructors and variables. Terminating narrowing sequences end up with the formula True, False or solved formulas that represent solutions of the initial formula (see section 3). Since the axioms are functional-logic programs in abstract logical syntax, rewriting and narrowing agree with program execution. Hence the medium level allows one to test such programs, while the inference rules of the top level provide a "tool box" for program verification. In the case of finite data sets, rewriting and narrowing is often sufficient even for program verification. Besides classical relations or deterministic functions, non-deterministic functions (e.g. state transition systems) and "distributed" transition systems like Maude programs [10] or algebraic nets [27] may also be axiomatized and verified by Expander2. The latter are executed by applying associative-commutative rewriting or narrowing on bag
terms, i.e. multisets of terms (see section 3).

At the bottom level, built-in Haskell functions simplify or (partially) evaluate terms and formulas and thereby hide most routine steps of proofs and computations. The functions comprise arithmetic, list, bag and set operations, term equivalence and inequivalence and logical simplifications (see section 5). Evaluating a function \( f \) at the medium level means narrowing upon the axioms for \( f \). Evaluating \( f \) at the bottom level means running a built-in Haskell implementation of \( f \). This allows one to test and debug algorithms and visualize their results. For instance, translators between different representations of Boolean functions were integrated into Expander2 in this way. In addition, an execution of an iterative algorithm can be split into its loop traversals such that intermediate results become visible. Currently, the computation steps of Gaussian equation solving, automata minimization, OBDD optimization, LR parsing, data flow analysis and global model checking can be carried out and displayed.

Section 3 presents the syntax of the axioms and theorems that can be handled by Expander2 and describes how they are applied to terms or formulas and how the applications build up proofs. Section 4 shows how axiom applications are combined to narrowing or rewriting steps. Section 5 goes into the logical details of the simplifier and lists the simplification rules for formulas. Section 6 provides induction, coinduction and other rules that Expander2 offers at the top level of interaction. The correctness of the rules presented in Sections 4, 5 and 6 follows almost immediately from corresponding soundness results given in \[16, 17, 18\]. The concluding section 7 focuses on future work.

3 Axioms, theorems, and derivations

Axioms and theorems to be applied in derivations are **Horn clauses** ((1)-(7)), **co-Horn clauses** ((8)-(12)) or **tautologies** ((13) and (14)):

(1) \{
\text{guard } \Rightarrow \}
(\{ f(\bar{t}) = u \} \iff \text{prem})
(2) \{
\text{guard } \Rightarrow \}
\left( t_1 \wedge \ldots \wedge t_n \rightarrow u \right) \iff \text{prem}
(3) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{f(\bar{t})}
(4) \{
\text{guard } \Rightarrow \}
\frac{t = u}{\text{prem}}
(5) \{
\text{guard } \Rightarrow \}
\frac{q(\bar{t})}{\text{prem}}
(6) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{a t_1 \wedge \ldots \wedge a t_n}
(7) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{a t_1 \vee \ldots \vee a t_n}
(8) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}
(9) \{
\text{guard } \Rightarrow \}
\frac{t = u}{\text{conc}}
(10) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}
(11) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}
(12) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}
(13) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}
(14) \{
\text{guard } \Rightarrow \}
\frac{\text{prem}}{\text{conc}}

Curly brackets enclose optional parts. \( f, p \) and \( q \) denote a defined function, a predicate and a copredicate, respectively, of the current signature. In the case of a higher-order symbol \( f, p \) or \( q \), \( (\bar{t}) \) may denote a “curried” tuple \((t_1) \ldots (t_n)\). Usually, \( a t_1, \ldots, a t_n \) are atoms, but may also be more complex formulas (see section 6).

The underlined terms or atoms are called **anchors**. Each application of a clause to a **redex**, i.e. a subterm or subformula of the current tree, starts with the search for a most general unifier of the redex and the anchor of the clause. If the unification is successful and the unifier satisfies the guard, then the redex is replaced by the **reduct**, i.e. the instance of \( \text{prem}, u \) or \( \text{conc} \), respectively, by the unifier. Moreover, the reduct is augmented with equations that represent the restriction of the unifier to the redex variables (see section 4). If the current trees are terms, then the reducts must be terms and thus only premise-free, but possibly guarded clauses of the form (1) or (2) can be applied.

A guarded clause is applied only if the instance of the guard by the unifier is solvable. The derived (most general) solution extends the unifier. Guarded axioms are needed for efficiently evaluating ground, i.e. variable-free, formulas. Axioms or theorems used as lemmas in proofs, however, should be unguarded.

Axioms represent functional-logic programs and thus are of the form (1), (2), (3) or (8). Axioms determine the least/greatest fixedpoint model of a specification (see section 1). Theorems are supposed to be valid in this model. Narrowing and rewriting consist of automatic axiom applications (see section 4). Applications of individual axioms are restricted to the top level of interaction (see section 6).

Axiom (2) can be applied to a bag term \( t = u_1 \ldots \wedge u_m \) if the list \([t_1, \ldots, t_n]\) unifies with a list \([u_{i_1}, \ldots, u_{i_m}]\) of elements of \( t \) such that \( 1 \leq i_1 \leq \ldots \leq i_n \leq m \), the unifier satisfies the guard and \( t \) is the
left-hand side of a transitional atom \( t \rightarrow t' \). This atom is then replaced by the formula

\[
\omega \sigma \land u_k \sigma \land \ldots \land u_{k_{m-n}} \sigma = t' \sigma \land \{ \text{prem} \sigma \}
\]

where \( \{k_1, \ldots, k_{m-n}\} = \{1, \ldots, m\} \setminus \{i_1, \ldots, i_n\} \). If the application of (2) to \( t \) fails, the elements of \( t \) are permuted. If after 100 permutations (2) is still inapplicable, the last permutation of \( a \) will be returned as result and yield a new starting point for further attempts to apply (2).

For applying a clause of type (1)-(5) or (8)-(10), select a term/atom \( at' \) with positive/negative polarity in the displayed tree such that the leading term/atom \( at \) is unifiable with \( at' \). \( at' \) is then replaced by the formula

\[
u \sigma \land u_k \sigma \land \ldots \land u_{k_m} \sigma = t' \sigma \land \{ \text{prem} \sigma \}
\]

For applying a clause of type (6), (7), (11) or (12), select \( n \) subformulas \( at_1', \ldots, at_n' \) of a disjunction/conjunction \( \varphi \) with positive/negative polarity in the displayed tree such that for all \( 1 \leq i \leq n \)

\( at_i' \) is unifiable with \( at_i \). The summands/factors of \( \varphi \) where \( at_1', \ldots, at_n' \) are selected from must not contain universal/existential quantifiers or negation or implication symbols. \( at_1', \ldots, at_n' \) are replaced by the corresponding instance of \( \text{prem/conc} \). The resulting summands/factors are combined conjunctively in the case of a Horn clause and disjunctively in the case of a co-Horn clause (see section 6).

For applying a tautology \( \text{conc} \) or \( \neg \text{prem} \), select a formula \( \varphi \) in the displayed tree and push the button transform selection/specialize. In cases (13) and (14), \( \varphi \) is replaced by \( \forall \vec{z} \text{conc} \Rightarrow \varphi \) resp. \( \neg \varphi \Rightarrow \exists \vec{z} \text{prem} \) where \( \vec{z} \) consists of the free variables of \( \text{conc} \) resp. \( \text{prem} \). The replacement is usually followed by a substitution of \( \vec{z} \) by terms \( \vec{t} \) of \( \varphi \), i.e., \( \forall \vec{z} \text{conc} \Rightarrow \varphi \) is turned into \( \text{conc}[\vec{t}/\vec{z}] \Rightarrow \varphi \), while \( \neg \varphi \Rightarrow \exists \vec{z} \text{prem} \) is turned into \( \neg \varphi \Rightarrow \text{prem}[\vec{t}/\vec{z}] \).

**Example 1** Finite lists are specified with a defined function flatten for flattening lists of lists and a predicate part for generating list partitions:

```plaintext
constructs: [] :
defuncts: flatten
preds: part >>
fovars: x y s s' s1 p
axioms:
part([x],[]): &
(part(x:y:s,[x]:p) <=== part(y:s,p)) &
(part(x:y:s,(x:s'):p) <=== part(y:s,s':p)) &
flatten([]) = [] &
flatten(s:p) = s++flatten(p) &
x >> x:s &
(s >> s' <=== s >> s1 & s1 >> s')
```

**Example 2** Streams (infinite lists) are specified with defined functions head, tail and eq, a constant stream blink and, given a Boolean function \( f \), a predicate exists(\( f \)) and a copredicate fair(\( f \)) that check whether \( f \) holds true for some element resp. infinitely many elements of the stream argument:

```plaintext
specs: NAT BOOL
columns: [] :
defuncts: head tail eq blink
def: exists
pred: fair
fovars: x y s
hovars: f
axioms:
head(x:s) = x &
tail(x:s) = s &
head(blink) = 0 &
tail(blink) = 1:blink &
eq(x)(x) = true &
(x =/= y ==> eq(x)(y) = false) &
(f(head(s)) = true ==> exists(f)(s)) &
(f(head(s)) = false ==> (exists(f)(s) <=== exists(f)(tail(s)))) &
(fair(f)(s) ==> exists(f)(s) & fair(f)(tail(s)))
```

**Example 3** Modal formulas are presented as first- or second-order state predicates (for least fixpoints) and copredicates (for greatest fixpoints). The binary predicate \( \rightarrow \) denotes the underlying labelled transition system:

```plaintext
constructs: a b
def: P true OD Y ->
cop: false OD X
```

\(^1\& and \mid denote conjunction and disjunction, respectively.\)
fovars: x st st'
hovars: P
axioms: true(st) &
    (false(st) ===> False) &
    (OD(x)(P)(st) <=<> (st,x) -> st' & P(st')) &
    (X(st) ===> Y(st)) &
    (X(st) ===> OB(b)(X)(st)) &
    (Y(st) <=<> OD(a)(true)(st)) &
    (Y(st) <=<> OD(b)(Y)(st)) &
    (2,b) -> 1 & (2,b) -> 3 & (3,b) -> 3 & (3,a) -> 4 & (4,b) -> 3

Example 4 Stack functions empty, push, pop and top are implemented in terms of array functions new, upd and get:

constructs: index entry new upd
defuncts: pred get empty push pop top
fovars: i j x f s s'
copreds: ~
axioms: pred(0) = 0 &
    pred(suc(i)) = i &
    get(new,i) = index(i) &
    get(upd(i,x,f),i) = entry(x) &
    (get(upd(i,x,f),j) = get(f,j) <=<> i /=/= j) &
    empty = (new,0) &
    push(x,(f,i)) = (upd(suc(i),x,f),suc(i)) &
    top(f,i) = get(f,i) &
    pop(f,i) = (f,pred(i)) &
    (s ~ s' <=<> top(s) = top(s') & pop(s) ~ pop(s'))

Example 5 Relational algebra

preds: Q R S O L I notI / /
folvors: x y z u
hovars: Q R S
axioms: L(x,y) &
    (I(x,y) <=<> x = y) &
    (notI(x,y) <=<> x /=/= y) &
    (R/S)(x,y) <=<> R(x,y) | S(x,y) &
    (C(R)(x,y) <=<> Not(R(x,y))) &
    (R+S)(x,y) <=<> R(x,z) & S(z,y) &
    (T(R)(x,y) <=<> R(y,x)) &
    ((R<=S)(x,y) <=<> (R(x,y) ==> S(x,y))) &
    ((R<=S)(x,y) <=<> (R<=S)(x,y) & (S<=R)(x,y)) &
    (dom(R)(x,y) <=<> R(x,z)) &
    star(R)(x,z) <=<> R(x,y) & star(R)(y,z) &
    (x >> y <=<> R(x,y)) &
    (x >> z <=<> R(x,y) & star(R)(y,z)) &

A derivation with Expander2 is a sequence of successive values of the state variable trees (see Section 2). It is stored in the state variables proof and proof term. All three variables are initialized when the contents of the text field is parsed and the resulting tree t is displayed on the canvas. Then the state variable trees is set to the singleton [t].

A derivation is correct if the derived disjunction/conjunction (resp. sum) of the current trees implies (resp. is a possible result of) the original one. The underlying semantics is described in section 1. Built-in symbols are interpreted by the simplifier. Expander2 checks the correctness of each derivation step and delivers a warning if the step may be incorrect.

A correct derivation that ends up with the formula True or False is a proof resp. refutation of the original formula ϕ. Further possible results are solved formulas, which are conjunctions of existentially quantified equations or universally quantified inequations that represent a substitution of the free variables of ϕ by normal forms (see section 2). The substitution is a solution of ϕ if the derivation of the solved formula is correct.

The correctness of a derivation step depends on the polarity of the redex with respect to its position within the current trees. The polarity is positive if the number of preceding formation symbols or premise positions is even. Otherwise it is negative. A rule is analytical or expanding if the reduct implies
the redex. Here the redex must have positive polarity if the derivation step shall be correct. A rule is **synthetical** or **contracting** if the redex implies the reduct. Here the redex must have negative polarity if the derivation step shall be correct. Expander2 checks these applicability conditions automatically. Of course, both analytical and synthetical rules transform a redex into an *equivalent* formula and thus may be applied regardless of the polarity.

## 4 Narrowing and rewriting

The narrowing procedure of Expander2 applies axioms and simplification rules repeatedly from top to bottom and from left to right, first to the currently displayed tree and then to other current trees. Usually, all applicable axioms for the anchor of a redex are applied simultaneously. Hence narrowing steps within a proof provide case distinctions.

Applying all applicable (Horn) axioms for a predicate or defined function simultaneously results in the replacement of the redex by the *disjunction* of their *premises* together with equations representing the computed unifiers (see Section 3). Applying all applicable (co-Horn) axioms for a copredicate simultaneously results in the replacement of the redex by the *conjunction* of their *conclusions*. The narrowing rules read as follows:

- **narrowing upon a predicate** \( p \neq \rightarrow \)

  \[
  p(t) \\
  \bigvee_{i=1}^{k} \exists Z_i : (\varphi_i \land \vec{x} = \vec{x}_{\sigma_i})
  \]

  where \( \gamma_1 \Rightarrow (p(t_1) \iff \varphi_1), \ldots, \gamma_n \Rightarrow (p(t_n) \iff \varphi_n) \) are the axioms for \( p \),

  \( \ast \) \( \vec{x} \) is a list of the variables of \( t \),

  for all \( 1 \leq i \leq k \), \( t_{\sigma_i} = t_i \sigma_i, \gamma_i \land \vec{x} = \vec{x}_{\sigma_i} \) and \( Z_i = \text{var}(t_i, \varphi_i) \),

  for all \( k < i \leq n \), \( t \) is not unifiable with \( t_i \).

- **narrowing upon a copredicate** \( p \)

  \[
  p(t) \\
  \bigwedge_{i=1}^{k} \forall Z_i : (\varphi_i \lor \vec{x} \neq \vec{x}_{\sigma_i})
  \]

  where \( \gamma_1 \Rightarrow (p(t_1) \implies \varphi_1), \ldots, \gamma_n \Rightarrow (p(t_n) \implies \varphi_n) \) are the axioms for \( p \) and \( \ast \) holds true.

- **narrowing upon a defined function** \( f \)

  \[
  r(\ldots, f(t), \ldots) \\
  \bigvee_{i=1}^{k} \exists Z_i : (r(\ldots, u_i, \ldots) \land \varphi_i \land \vec{x} = \vec{x}_{\sigma_i}) \lor \\
  \bigvee_{i=k+1}^{l} (r(\ldots, f(t), \ldots) \land \vec{x} = \vec{x}_{\sigma_i})
  \]

  where \( r \) is a predicate or copredicate,

  \( \gamma_1 \Rightarrow (f(t_1) = u_1 \iff \varphi_1), \ldots, \gamma_n \Rightarrow (f(t_n) = u_n \iff \varphi_n) \) are the axioms for \( f \),

  \( \ast \ast \) \( \vec{x} \) is a list of the variables of \( t \),

  for all \( 1 \leq i \leq k \), \( t_{\sigma_i} = t_i \sigma_i, \gamma_i \land \vec{x} = \vec{x}_{\sigma_i} \) and \( Z_i = \text{var}(t_i, \varphi_i) \),

  for all \( k < i \leq l \), \( \sigma_i \) is a partial unifier of \( t \) and \( t_i \),

  for all \( l < i \leq n \), \( t \) is not partially unifiable with \( t_i \).

- **narrowing upon the predicate** \( \rightarrow \)

  \[
  t \land v \rightarrow t' \\
  \bigvee_{i=1}^{k} \exists Z_i : ((u_i \land v) \lor \vec{x} = \vec{x}_{\sigma_i}) \lor \\
  \bigvee_{i=k+1}^{l} (t \land t_i \land \vec{x} = \vec{x}_{\sigma_i})
  \]

  where \( \gamma_1 \Rightarrow (t_1 \rightarrow u_1 \iff \varphi_1), \ldots, \gamma_n \Rightarrow (t_n \rightarrow u_n \iff \varphi_n) \) are the axioms for \( \rightarrow \), \( \ast \ast \ast \) holds true and \( \sigma_i \) is a unifier *modulo associativity and commutativity of* \( \land \)

- **elimination of non-narrowable atoms and terms**

  \[
  p(t) \quad q(t) \quad r(\ldots, f(t), \ldots) \\
  \text{False} \quad \text{True} \quad r(\ldots, (), \ldots) \\
  t \rightarrow t'
  \]

  where \( p \neq \rightarrow \) is a predicate, \( q \) is a copredicate, \( r \) is a predicate or copredicate, \( f \) is a defined function, \( t \) is a normal form and for all axioms \( \gamma \Rightarrow (p(u) \iff \varphi), \gamma \Rightarrow (q(u) \implies \varphi), \gamma \Rightarrow (f(u) = v \iff \varphi) \) and \( \gamma \Rightarrow (u \rightarrow v \iff \varphi) \), \( t \) and \( u \) are not unifiable.

\[ ^2 \]Hence \( \sigma_i \) solves the guard \( \gamma_i \). Expander2 tries to solve \( \gamma_i \) by applying at most 100 narrowing steps.
u_1, \ldots, u_n may be tuples of terms. In the case of narrowing upon a defined function, the unification of \( t \) with \( u_i \) may fail because at some position, the root symbols of \( t \) and \( u_i \) are different and one of them is a defined function \( f \). Since the unification may succeed later, when subsequent narrowing steps have replaced \( f \) by a constructor or a variable, we save the already obtained partial unifier \( \sigma_i \) and construct a reduct that consists of the \( \sigma_i \)-instance of the redex and equations that represent \( \sigma_i \). This version of the narrowing rule has been derived from the needed narrowing strategy \([1, 16]\). If the underlying specification is functional, the strategy of applying these narrowing rules iteratively from top to bottom to a formula \( \varphi \) leads to a set \( S \) of solutions of \( \varphi \) such that each solution of \( \varphi \) is an instance of some \( s \in S \) \([17, 18]\). Hence, in the context of this strategy, the narrowing rules are equivalence transformations.

If the current trees are terms, only rewriting steps can be applied. Rewriting is the special case of narrowing upon defined functions where the unifiers \( \sigma_i \) do not instantiate redex variables:

- **rewriting upon a defined function** \( f \)

\[
\frac{c(f(t))}{c(u_1 \sigma_1) \leftarrow \ldots \leftarrow c(u_k \sigma_k)}
\]

where \( \gamma_1 \Rightarrow f(t_1) = u_1, \ldots, \gamma_1 \Rightarrow f(t_n) = u_n \) are the axioms for \( f \) and

\( (*) \quad \text{for all } 1 \leq i \leq k, t_i = t_i \sigma_i \text{ and } \gamma_i \sigma_i \vdash \text{True}, \)

for all \( k < i \leq n, t \) does not match \( t_i \).

- **rewriting upon the predicate** \( \rightarrow \)

\[
\frac{c(t)}{c(u_1 \sigma_1) \leftarrow \ldots \leftarrow c(u_k \sigma_k)}
\]

where \( \gamma_1 \Rightarrow t_1 \rightarrow u_1, \ldots, \gamma_1 \Rightarrow t_n \rightarrow u_n \) are the axioms for \( \rightarrow \) and \( (*) \) holds true.

- **elimination of non-rewritable terms**

\[
\frac{f(t)}{()}
\]

where \( f \) is a defined function, \( t \) is a normal form and for all axioms \( \gamma \Rightarrow f(u) = v \) and \( \gamma \Rightarrow u \rightarrow v, t \) and \( u \) are not unifiable.

5 **Simplification**

Narrowing removes predicates, copredicates and defined functions from the current trees. The simplifier does the same with logical operators, constructors and symbols of the built-in signature. Simplifications realize the highest degree of automation and the lowest degree of interaction (see section 2). The reducts of rewriting or narrowing steps are simplified automatically.

The evaluation rules used by the simplifier are equivalence transformations. Besides the partial evaluation of built-in predicates and functions, the following rules are applied:

- **True and False**

\[
\begin{align*}
\varphi \land \text{True} & \quad \varphi \lor \text{False} \\
\varphi & \quad \text{False} \\
\varphi \land \text{False} & \quad \varphi \lor \text{True} \\
(\_) & \rightarrow t
\end{align*}
\]

- **Sum propagation.** Let \( f \) be a function and \( r \) be a relation.

\[
\begin{align*}
f(...) & \leftarrow \ldots \leftarrow t_n, \ldots) \\
f(...) & \leftarrow \ldots \leftarrow f(...) \\
\rightarrow \ldots \rightarrow r(...) & \leftarrow \ldots \leftarrow t_n, \ldots)
\end{align*}
\]

- **Equation or inequation splitting.** Let \( c \) and \( d \) be different constructors.

\[
\begin{align*}
c(t_1, \ldots, t_n) = c(u_1, \ldots, u_n) & \quad c(t_1, \ldots, t_n) = d(u_1, \ldots, u_n) \\
t_1 = u_1 \land \ldots \land t_n = u_n & \quad \text{False}
\end{align*}
\]

\[
\begin{align*}
c(t_1, \ldots, t_n) \neq c(u_1, \ldots, u_n) & \quad c(t_1, \ldots, t_n) \neq d(u_1, \ldots, u_n) \\
t_1 \neq u_1 \lor \ldots \lor t_n \neq u_n & \quad \text{True}
\end{align*}
\]

- **Quantifier movement**

\[
\begin{align*}
\forall \bar{x}(\varphi_1 \land \ldots \land \varphi_n) & \quad \exists \bar{x}((\varphi_1 \lor \ldots \lor \varphi_n) \\
\exists \bar{x}(\varphi_1 \land \ldots \land \varphi_n) & \quad \exists \bar{x}((\varphi_1 \lor \ldots \lor \varphi_n) \\
\forall \bar{x}\varphi \Rightarrow \exists \bar{x}\psi & \quad \forall \bar{x}\varphi \Rightarrow \exists \bar{x}\psi
\end{align*}
\]

9
Let $\vec{x} = \theta(\vec{x}_1 \cup \ldots \cup \vec{x}_n)$ and $\theta$ be a renaming of variables such that for all $1 \leq i \leq n$, no variable of $\theta(\vec{x}_i)$ occurs freely in some $\theta(\phi_j)$, $1 \leq j \leq n$, $j \neq i$.

\[
\begin{align*}
\exists \vec{x}_1 \phi_1 \wedge \ldots \wedge \exists \vec{x}_n \phi_n \\
\exists \theta(\phi_1 \wedge \ldots \wedge \phi_n) \\
\forall \vec{x}_1 \phi_1 \lor \ldots \lor \forall \vec{x}_n \phi_n \\
\forall \theta(\phi_1 \lor \ldots \lor \phi_n) \\
\exists \vec{x}_1 \phi_1 \Rightarrow \forall \vec{x}_2 \phi_2 \\
\forall \theta(\phi_1 \Rightarrow \phi_2)
\end{align*}
\]

- **Removal of negation.** Negation symbols are moved to literal positions where they are replaced by complement predicates: $\neg P(t)$ is reduced to $\text{not}_P(t)$, $\neg \text{not}_P(t)$ is reduced to $P(t)$. Co-Horn/Horn axioms for $\text{not}_P$ can be generated automatically from Horn/Co-Horn axioms for $P$.

- **Removal of quantifiers.** Unused bounded variables are removed. Successive quantifiers are merged.

- **Subsumption.** Suppose that $\phi$ subsumes $\psi$.

\[
\begin{align*}
\varphi \Rightarrow \psi & \quad \Rightarrow \varphi \text{ subsumes } \psi \\
\varphi \text{ subsumes } \psi & \quad \Rightarrow \neg \psi \text{ subsumes } \neg \varphi \\
\varphi' \text{ subsumes } \varphi \text{ and } \psi \text{ subsumes } \psi' & \quad \Rightarrow \varphi \Rightarrow \psi \text{ subsumes } \varphi' \Rightarrow \psi' \\
\exists 1 \leq i \leq n : \varphi_i \text{ subsumes } \psi_i & \quad \Rightarrow \varphi \text{ subsumes } \psi_1 \lor \ldots \lor \psi_n \\
\forall 1 \leq i \leq n : \varphi_i \text{ subsumes } \psi_i & \quad \Rightarrow \varphi \text{ subsumes } \psi_1 \lor \ldots \lor \psi_n \\
\forall 1 \leq i \leq n : \varphi_i \text{ subsumes } \psi_i & \quad \Rightarrow \varphi \text{ subsumes } \psi_1 \lor \ldots \lor \psi_n \\
\exists 1 \leq i \leq n : \varphi_i \text{ subsumes } \psi_i & \quad \Rightarrow \varphi_1 \lor \ldots \lor \varphi_n \text{ subsumes } \psi \\
\varphi(\vec{x}) \text{ subsumes } \psi(\vec{x}) & \quad \Rightarrow \exists \vec{y} \varphi(\vec{x}) \text{ subsumes } \exists \vec{y} \psi(\vec{y}) \\
\varphi(\vec{x}) \text{ subsumes } \psi(\vec{x}) \text{ and no variable of } \vec{x} \text{ occurs freely in } \psi & \quad \Rightarrow \exists \vec{y} \varphi(\vec{x}) \text{ subsumes } \psi \\
\varphi(\vec{x}) \text{ subsumes } \psi(\vec{x}) \text{ and no variable of } \vec{y} \text{ occurs freely in } \varphi & \quad \Rightarrow \varphi \text{ subsumes } \exists \vec{y} \psi(\vec{y}) \\
\exists \vec{x} : \phi \sim \psi(\vec{t}) & \quad \Rightarrow \exists \vec{x} \varphi(\vec{x}) \text{ subsumes } \exists \vec{x} \psi(\vec{x}) \\
\exists \vec{x} : \phi(\vec{t}) \sim \psi & \quad \Rightarrow \forall \vec{x} \varphi(\vec{x}) \text{ subsumes } \psi \\
\exists \vec{x}, \{i_1, \ldots, i_k\} \subset \{1, \ldots, n\} : \phi_{i_1} \wedge \ldots \wedge \phi_{i_k} \sim \psi(t) & \quad \Rightarrow \phi_1 \wedge \ldots \wedge \phi_n \text{ subsumes } \exists \vec{x} \psi(\vec{x}) \\
\exists \vec{x}, \{i_1, \ldots, i_k\} \subset \{1, \ldots, n\} : \phi(t) \sim \psi_{i_1} \lor \ldots \lor \psi_{i_k} & \quad \Rightarrow \forall \vec{x} \varphi(\vec{x}) \text{ subsumes } \psi_1 \lor \ldots \lor \psi_n
\end{align*}
\]

- **Elimination of equations and inequations.** Let $x \in \vec{x} \setminus \text{var}(t)$.

\[
\begin{align*}
\exists \vec{x} (x = t \land \varphi) & \quad \Rightarrow \exists \vec{x} \varphi(t/x) \\
\forall \vec{x} (x \neq t \lor \varphi) & \quad \Rightarrow \forall \vec{x} \varphi(t/x) \\
\forall \vec{x} (x = t \land \varphi \Rightarrow \psi) & \quad \Rightarrow \forall \vec{x} (\varphi \Rightarrow x \neq t \lor \psi) \\
\forall \vec{x} (\varphi \Rightarrow \psi|t/x) & \quad \Rightarrow \forall \vec{x} (\varphi \Rightarrow \psi)|t/x
\end{align*}
\]

- **Internal application of equations or inequations.**

Let $\text{root}(t)$ be a constructor and $\text{root}(u)$ not be a constructor.

\[
\begin{align*}
t = u \land \varphi(t) & \quad \Rightarrow \psi(t) \\
t = u \land \varphi(u) & \quad \Rightarrow \varphi(t) \Rightarrow t \neq u \lor \psi(t) \\
t = u \land \varphi(u) & \quad \Rightarrow \varphi(u) \Rightarrow t \neq u \lor \psi(u)
\end{align*}
\]

- **Implication splitting**

\[
\begin{align*}
\forall \vec{x} (\varphi_1 \lor \ldots \lor \varphi_n \Rightarrow \psi) & \quad \Rightarrow \forall \vec{x} (\varphi_1 \Rightarrow \psi) \wedge \ldots \wedge \forall \vec{x} (\varphi_n \Rightarrow \psi) \\
\forall \vec{x} (\varphi \Rightarrow \psi_1 \ldots \land \psi_n) & \quad \Rightarrow \forall \vec{x} (\varphi \Rightarrow \psi_1 \lor \ldots \lor \psi_n)
\end{align*}
\]
• Uncurrying

$$\varphi \Rightarrow (\theta \Rightarrow \psi_1) \lor \psi_2$$

$$\varphi \land \theta \Rightarrow \psi_1 \lor \psi_2$$

Besides being an essential part of proof processes, simplification in Expander2 may be used for testing algorithms, especially iterative ones, which change values of state terms during loop traversals [22]. Several such algorithms have been integrated into the simplifier by translating a loop traversal into a simplification step. Consequently, intermediate results can be visualized in a painter window (see Section 2). The respective state terms are created by applying particular equational axioms.

Similarly to narrowing and rewriting, the simplifier pursues a top-down strategy that ensures termination and the eventual application of all applicable rules. This is necessary because it usually works in the background. For instance, narrowing reducts are simplified automatically before they are submitted to further narrowing steps.

The notion of simplification differs from prover to prover. For instance, Isabelle [13] subsumes rewriting upon equational axioms under simplification.

6 Rules at the top level of interaction

Narrowing steps and simplifications are both analytical and synthetical and thus turn formulas into semantically equivalent ones. Instances of the rules that are accessible via the solver’s selection menu (see Fig. ??), however, may be strictly analytical or strictly synthetical. Hence they can be applied only individually and only to subtrees with positive resp. negative polarity (see Section 3). We describe the main rules in terms of the actions to be taken by the user in order to apply them.

• Instantiation. Select an existentially/universally quantified variable $x$. If the scope of $x$ has positive/negative polarity, then all occurrences of $x$ in the scope are replaced by the term in the solver’s entry field. Alternatively, the replacing term $t$ may be taken from the displayed tree and moved to a position of $x$ in the scope. Again, all occurrences of $x$ in the scope are replaced by $t$.

• Generalization. Select a subformula $\varphi$ and enter a formula $\psi$ into the solver’s entry field. If $\varphi$ has positive/negative polarity, then $\varphi$ is combined conjunctively/disjunctively with $\psi$.

• Unification. Select two factors of a conjunction $\varphi = \exists \vec{\varphi} \land \varphi_n$ or two summands of a disjunction $\psi = \forall \vec{\varphi} \lor \varphi_n$. If they are unifiable and the unifier instantiates only variables of $\vec{x}$, then one of them is removed and the unifier is applied to the remaining conjunction/disjunction.

The transformation is correct if $\varphi/\psi$ has positive/negative polarity.

• Copy. Select a subtree $\varphi$. A copy of $\varphi$ is added to the children of the subtree’s parent node. The transformation is correct if the parent node holds a conjunction or disjunction symbol.

• Removal. Select subtrees $\phi_1, \ldots, \phi_n$. $\phi_1, \ldots, \phi_n$ are removed from the displayed tree. The transformation is correct if $\phi_1, \ldots, \phi_n$ are summands/factors of the same disjunction/conjunction with positive/negative polarity.

• Reversal. The list of selected subtrees is reversed. The transformation is correct if all subtrees are arguments of the same occurrence of a permutative operator. Currently, the permutative operators are:

$\&\, \mid, =, = / =, \sim, \sim / \sim, +, \sim, \sim, \sim, \{\}.$

• Atom decomposition.

$$\frac{f(t_1, \ldots, t_n) = f(u_1, \ldots, u_n)}{t_1 = u_1 \land \ldots \land t_n = u_n} \uparrow \quad \frac{f(t_1, \ldots, t_n) \neq f(u_1, \ldots, u_n)}{t_1 \neq u_1 \lor \ldots \lor t_n \neq u_n} \downarrow$$

• Internal application of equations or inequations.

$$\frac{t = u \land \varphi(t)}{t = u \land \varphi(u)} \Downarrow \quad \frac{t \neq u \lor \varphi(t)}{t \neq u \lor \varphi(u)} \Uparrow$$

$$\frac{t = u \land \varphi(t) \Rightarrow \psi(t)}{t = u \land \varphi(u) \Rightarrow \psi(u)} \Downarrow \quad \frac{\varphi(t) \Rightarrow t \neq u \lor \psi(t)}{\varphi(u) \Rightarrow t \neq u \lor \psi(u)} \Uparrow$$

• Transitivity. Select an atom $t \mathbin{R} t'$ with positive polarity or $n - 1$ factors

$$t_1 \mathbin{R} t_2, \ t_2 \mathbin{R} t_3, \ldots, \ t_\mathbin{R} t_n$$

of a conjunction with negative polarity such that $R$ is among $\langle, \leq, \geq, =, \sim$. The selected atoms are decomposed resp. composed in accordance with the assumption that $R$ is transitive.

• Constrained narrowing. Select subtrees $\phi_1, \ldots, \phi_n$ and write axioms into the text field or a signature symbol $f$ into the solver’s entry field. Then narrowing/rewriting steps upon the axioms in the text field or the axioms for $f$, respectively, are applied to $\phi_1, \ldots, \phi_n$. 

11
• **Axiom/theorem application.** Select subtrees $\phi_1, \ldots, \phi_n$ and write the number of an axiom or theorem into the solver’s entry field. The selected axiom or theorem $\psi$ is applied from left to right or from right to left to $\phi_1, \ldots, \phi_n$. Left/right refers to $t$ resp. $u$ if $\psi$ has the form $tru \iff prem$ where $R$ is symmetric and to the formula left/right of $\iff$ resp. $\implies$ in all other cases. The transformation is correct if the conclusion/premise of $\psi$ has positive/negative polarity.

A clause of type (6), (7), (11) or (12) is applied to atoms $at_1', \ldots, at_n'$ each of which is part of a conjunction or disjunction: Let $z$ consist of the free variables of $prem$ resp. $conc$ that do not occur in $at_1, \ldots, at_n$.

1. **Application of (6).**
   \[
   \frac{\varphi_1(at_1') \land \ldots \land \varphi_n(at_n')}{(\bigwedge_{i=1}^n \varphi_i(\exists z (prem \land \bigwedge_{x \in \text{dom}(\sigma)} x \equiv x \sigma)))} \uparrow
   \]
   where for all $1 \leq i \leq n$, $at_i' \sigma = at_i \sigma$ and $\varphi_i$ does not contain existential quantifiers or negation or implication symbols.

2. **Application of (7).**
   \[
   \frac{\varphi_1(at_1') \lor \ldots \lor \varphi_n(at_n')}{(\bigwedge_{i=1}^n \varphi_i(\exists z (prem \land \bigwedge_{x \in \text{dom}(\sigma)} x \equiv x \sigma)))} \uparrow
   \]
   where for all $1 \leq i \leq n$, $at_i' \sigma = at_i \sigma$ and $\varphi_i$ does not contain universal quantifiers or negation or implication symbols.

3. **Application of (11).**
   \[
   \frac{\varphi_1(at_1') \land \ldots \land \varphi_n(at_n')}{(\bigwedge_{i=1}^n \varphi_i(\forall z (\bigwedge_{x \in \text{dom}(\sigma)} x \equiv x \sigma \implies conc \sigma)))} \downarrow
   \]
   where for all $1 \leq i \leq n$, $at_i' \sigma = at_i \sigma$ and $\varphi_i$ does not contain existential quantifiers or negation or implication symbols.

4. **Application of (12).**
   \[
   \frac{\varphi_1(at_1') \lor \ldots \lor \varphi_n(at_n')}{(\bigwedge_{i=1}^n \varphi_i(\forall z (\bigwedge_{x \in \text{dom}(\sigma)} x \equiv x \sigma \implies conc \sigma)))} \downarrow
   \]
   where for all $1 \leq i \leq n$, $at_i' \sigma = at_i \sigma$ and $\varphi_i$ does not contain universal quantifiers or negation or implication symbols.

• **Noetherian induction.** Select a list of free or universal induction variables $x_1, \ldots, x_n$ in the displayed tree. If $\varphi = (prem \implies conc)$, then the induction hypotheses

   \[
   \begin{align*}
   \text{conc}' & \iff (x_1, \ldots, x_n) \not\equiv (x_1', \ldots, x_n') \land prem' \\
   \text{prem}' & \implies ((x_1, \ldots, x_n) \not\equiv (x_1', \ldots, x_n') \implies \text{conc}')
   \end{align*}
   \]

   are added to the current theorems. If $\varphi$ is not an implication, then

   \[
   \text{conc}' \iff (x_1, \ldots, x_n) \not\equiv (x_1', \ldots, x_n')
   \]

   is added. Primed formulas are obtained from unprimed ones by priming the occurrences of $x_1, \ldots, x_n$. $\not\equiv$ denotes the induction ordering. Each left-to-right application of an added theorem corresponds to an induction step and introduces an occurrence of $\not\equiv$. After axioms for $\not\equiv$ have been added to the current axioms, narrowing steps upon $\not\equiv$ should remove the occurrences of $\not\equiv$ because the transformation is correct only if $\varphi$ can be derived to True [15, 16].

• **Vertical shift of quantifiers.** Select quantified arguments of a propositional operator $op$, i.e. $op \in \{\land, \lor, \neg, \not\equiv\}$. The quantifiers are shifted in front of $op$ after all bound variables that also occur freely in some argument or in more than one argument of $op$ have been renamed. For instance, a clause of type (6) or (11) cannot be applied to existentially quantified factors and a clause of type (7) or (12) cannot be applied to universally quantified summands (see above). Hence moving the quantifiers out of the conjunction resp. disjunction may be necessary.

• **Horizontal shift of subformulas.** Select an implication

   \[
   \text{prem}_1 \land \ldots \land \text{prem}_m \implies \text{conc}_1 \lor \ldots \lor \text{conc}_n,
   \]

   premises $\text{prem}_i$, $\text{prem}_i'$ and/or conclusions $\text{conc}_j, \ldots, \text{conc}_j'$. The implication is turned into

   \[
   \begin{align*}
   \text{prem}_1 \land \ldots \land \text{prem}_m \land \neg \text{conc}_j \land \ldots \land \neg \text{conc}_j' & \implies \neg \text{prem}_1 \lor \ldots \lor \neg \text{prem}_m \lor \text{conc}_j' \lor \ldots \lor \text{conc}_j' \\
   \end{align*}
   \]

   where $i_1', \ldots, i_k' = \{1, \ldots, m\} \setminus \{i_1, \ldots, i_k\}$ and $j_1', \ldots, j_k' = \{1, \ldots, n\} \setminus \{j_1, \ldots, j_k\}$. Such a transformation may be necessary if the original implication shall be proved by fixpoint induction or coinduction (see below).
The following rules are correct if the selected subformulas have positive polarity. For each predicate, copredicate or function \( p \), let \( AX_p \) be the set of axioms for \( p \).

- **Coinduction on a copredicate** \( p \). Select subformulas

\[
\begin{align*}
\{ \text{prem}_1 \Rightarrow \} & \quad p(t_1) \\
\land & \quad \ldots \\
\land & \quad \{ \text{prem}_k \Rightarrow \} \quad p(t_k)
\end{align*}
\]

such that \( p \) does not depend on any predicate or function occurring in \( \text{prem}_i \). A is turned into

\[
p(x) \iff \{ \text{prem}_1 \land \} \quad x = t_1 \\
\land & \quad \ldots \\
\land & \quad \{ \text{prem}_k \land \} \quad x = t_k
\]

where \( x \) is a list of variables. Moreover, a new predicate \( p' \) is added to the current signature and

\[
p'(x) \iff \{ \text{prem}_1 \land \} \quad x = t_1 \\
\land & \quad \ldots \\
\land & \quad \{ \text{prem}_k \land \} \quad x = t_k
\]

becomes the axiom for \( p' \). \(^*\) is applied to \( AX_p[p'/p] \). The conjunction of the resulting clauses replaces the original conjecture A.

- **Fixpoint induction on a predicate** \( p \). Select subformulas

\[
\begin{align*}
p(t_1) & \Rightarrow \text{conc}_1 \\
\land & \quad \ldots \\
p(t_k) & \Rightarrow \text{conc}_k
\end{align*}
\]

such that \( p \) does not depend on any predicate or function occurring in \( \text{conc}_i \). B is turned into

\[
p(x) \implies (x = t_1 \Rightarrow \text{conc}_1) \\
\land & \quad \ldots \\
\land & \quad (x = t_k \Rightarrow \text{conc}_k)
\]

where \( x \) is a list of variables. Moreover, a new predicate \( p' \) is added to the current signature and

\[
p'(x) \implies (x = t_1 \Rightarrow \text{conc}_1) \\
\land & \quad \ldots \\
\land & \quad (x = t_k \Rightarrow \text{conc}_k)
\]

becomes the axiom for \( p' \). \(^*\) is applied to \( AX_p[p'/p] \). The conjunction of the resulting clauses replaces the original conjecture B.

- **Fixpoint induction on a function** \( f \). Select subformulas

\[
\begin{align*}
f(t_1) & = u_1 \Rightarrow \text{conc}_1 \\
\land & \quad \ldots \\
f(t_k) & = u_k \Rightarrow \text{conc}_k
\end{align*}
\]

or

\[
\begin{align*}
f(t_1) & = u_1 \land \text{conc}_1 \\
\land & \quad \ldots \\
f(t_k) & = u_k \land \text{conc}_k
\end{align*}
\]

such that \( f \) does not depend on any predicate or function occurring in \( u_i \) or \( \text{conc}_i \). C is turned into

\[
f(x) = z \implies (x = t_1 \land z = u_1 \Rightarrow \text{conc}_1) \\
\land & \quad \ldots \\
\land & \quad (x = t_k \land z = u_k \Rightarrow \text{conc}_k),
\]

\(^{C'}\) is applied to \( AX_p[u_i \land \text{conc}_i] \). D is turned into

\[
f(x) = z \implies (x = t_1 \Rightarrow z = u_1 \land \text{conc}_1) \\
\land & \quad \ldots \\
\land & \quad (x = t_k \Rightarrow z = u_k \land \text{conc}_k)
\]

\(^{D'}\)
where \( \vec{x} \) is a list of variables and \( z \) is a variable. Moreover, a new predicate \( f' \) is added to the current signature and
\[
f'(\vec{x}, z) \implies (\vec{x} = \vec{t}_1 \land z = t_1) \implies \text{conc}_1 \\
\land \ldots \\
\land (\vec{x} = \vec{t}_k \land z = t_k) \implies \text{conc}_k
\]
resp.
\[
f'(\vec{x}, z) \implies (\vec{x} = \vec{t}_1 \implies (z = t_1 \{\text{conc}_1\})) \\
\land \ldots \\
\land (\vec{x} = \vec{t}_k \implies (z = t_k \{\text{conc}_k\}))
\]  

becomes the axiom for \( f' \). (*) is applied to \( \text{flat}(\text{AX}_f)[f'/f(\_ \equiv \_)] \). The conjunction of the resulting clauses replaces the original conjecture C/D.

- **Hoare induction.** Select a subformula of the form

\[
f(t_1, \ldots, t_n) = t \Rightarrow \text{conc} \quad (A)
\]

or

\[
f(t_1, \ldots, t_n) = t \{\land \text{conc}\} \quad (B)
\]

such that \( f \) has a single axiom of the form

\[
f(x_1, \ldots, x_n) = g(u_1, \ldots, u_k)
\]

or, if the term \( t_i \) in A/B has been selected (in addition to A/B itself), \( f \) has a single axiom of the form

\[
f(x_1, \ldots, x_n) = g(x_1, \ldots, x_n, u_1, \ldots, u_k)
\]

with distinct variables \( x_1, \ldots, x_n \). A is turned into \( \text{INV1} \land \text{INV2} \) where

\[
\begin{align*}
\text{INV}(x_1, \ldots, x_n, u_1, \ldots, u_k) \\
g(x_1, \ldots, x_n, y_1, \ldots, y_k) = z \land \text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k) \\
\implies (x_1 = t_1 \land \ldots \land x_n = t_n \land x = t \Rightarrow \text{conc})
\end{align*}
\]

(\text{INV1})

while B is turned into \( \text{INV1} \land \text{INV3} \) where

\[
\begin{align*}
\text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k) \\
g(x_1, \ldots, x_n, y_1, \ldots, y_k) = z \land \text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k) \\
\implies (x_1 = t_1 \land \ldots \land x_n = t_n \Rightarrow x = t \{\land \text{conc}\})
\end{align*}
\]

(\text{INV2})

(\text{INV3})

If \( t_i \) has not been selected in A/B, then \( g(x_1, \ldots, x_n, y_1, \ldots, y_k) \) reduces to \( g(y_1, \ldots, y_k) \). Usually, the proof proceeds by narrowing INV1, shifting

\[
\text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k)
\]

from the premise to the conclusion of INV2/INV3 and submitting the resulting formula to fixpoint induction.

- **Subgoal induction** works the same as Hoare induction except that a selected conjecture of the form \( A \) is turned into \( \text{INV1} \land \text{INV2} \) where

\[
\begin{align*}
\text{INV}(x_1, \ldots, x_n, u_1, \ldots, u_k, z) \\
\implies (x_1 = t_1 \land \ldots \land x_n = t_n \land x = t \Rightarrow \text{conc})
\end{align*}
\]

(\text{INV1})

\[
\begin{align*}
\text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k, z) \\
g(x_1, \ldots, x_n, y_1, \ldots, y_k) = z \Rightarrow \text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k, z)
\end{align*}
\]

(\text{INV2})

while a selected conjecture of the form \( B \) is turned into \( \text{INV1} \land \text{INV3} \) where

\[
\begin{align*}
\text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k) \\
g(x_1, \ldots, x_n, y_1, \ldots, y_k) = z \Rightarrow \text{INV}(x_1, \ldots, x_n, y_1, \ldots, y_k, z)
\end{align*}
\]

(\text{INV3})

Usually, the proof proceeds by narrowing INV1 and submitting INV2/INV3 to fixpoint induction.

## 7 Sample proofs

**Example 1 (continued; see section 3)** An Expander2 proof by fixpoint induction is presented. The conjecture says that \( \text{part} \) returns only partitions of the given list.\(^3\).

\(^3\text{All} \) and \text{Any} denote universal and existential quantification, respectively
part(s,p) ==> s = flatten(p)

Applying fixpoint induction w.r.t.

   part([x],[[x]])
& (part(x:y:s,[x]:p) <= part(y:s,p))
& (part(x:y:s,x:s':p) <= part(y:s,s':p))

at position [] of the preceding formula leads to

All x:([x] = flatten([x])) &
All x y s p:(y:s = flatten(p) ==> x:y:s = flatten([x]:p)) &
All x y s p s':(y:s = flatten(s':p) ==> x:y:s = flatten(x:s':p))

The reducts have been simplified.

Applying the axiom resp. theorem

flatten(s:p) = s++flatten(p)

at positions [2,0,1,1],[2,0,0,1],[1,0,1,1],[0,0,1] of the preceding formula leads to

[] = flatten[]

The reducts have been simplified.

Narrowing the preceding formula leads to

True

A proof by Noetherian induction of the same conjecture is less straightforward and needs more interaction. The induction hypothesis must be applied two times:

part(s,p) ==> s = flatten(p)

Selecting induction variables at position [0,0] of the preceding formula leads to

All p:(part(!s,p) ==> !s = flatten(p))

Applying the axioms

   flatten[] = []
& flatten(s:p) = s++flatten(p)
& part([x],[[x]])
& (part(x:y:s,[x]:p) <= part(y:s,p))
& (part(x:y:s,x:s':p) <= part(y:s,s':p))

at positions [0,1,1],[0,0] of the preceding formula leads to

All x:(!s = [x] ==> [] = flatten[]) &
All x y s p0:(!s = x:y:s & part(y:s,p0) ==> y:s = flatten(p0)) &
All x y s s':(s' = x:y:s & part(y:s,s':p0) ==> y:s = s'++flatten(p0))

The reducts have been simplified.

Applying the axiom resp. theorem

flatten[] = []

at position [0,0,1,1] of the preceding formula leads to

All x y s p0:(s = x:y:s & part(y:s,p0) ==> y:s = flatten(p0)) &
All x y s s':(s' = x:y:s & part(y:s,s':p0) ==> y:s = s'++flatten(p0))

The reducts have been simplified.

Shifting subformulas at position [0,0,0,1] of the preceding formula leads to
All \( x \ y \ s \ p0: (s = x:y:s \iff (part(y:s,p0) \iff y:s = flatten(p0))) \) &
All \( x \ y \ s \ s' \ p0: (s = x:y:s \& part(y:s, s':p0) \iff y:s = s'++flatten(p0)) \)

Applying the induction hypothesis
\[ part(s, p) \iff (!s \gg s \iff s = flatten(p)) \]

at position \([0,0,1,0]\) of the preceding formula leads to
\[ \text{All } x \ y \ s \ p0: (s = x:y:s \& (x:y:s \gg y:s \iff y:s = flatten(p0)) \iff y:s = flatten(p0)) \] &
\[ \text{All } x \ y \ s \ s' \ p0: (s = x:y:s \& part(y:s, s':p0) \iff y:s = s'++flatten(p0)) \]

The reducts have been simplified.

Applying the axioms
\[ x:s \gg s \& (x \gg y \iff x > y) \]

at position \([0,0,0,1,0]\) of the preceding formula leads to
\[ \text{All } x \ y \ s \ s' \ p0: (s = x:y:s \& (x:y:s \gg y:s \iff y:s = flatten(s':p0)) \iff y:s = s'++flatten(p0)) \]

Applying the induction hypothesis
\[ part(s, p) \iff (!s \gg s \iff s = flatten(p)) \]

at position \([0,1,0]\) of the preceding formula leads to
\[ \text{All } x \ y \ s \ s' \ p0: (s = x:y:s \& (x:y:s \gg y:s \iff y:s = flatten(s':p0)) \iff y:s = s'++flatten(p0)) \]

The reducts have been simplified.

Applying the axioms
\[ x:s \gg s \& (x \gg y \iff x > y) \]

at position \([0,0,1,0]\) of the preceding formula leads to
\[ \text{All } x \ y \ s \ s' \ p0: (s = x:y:s \& y:s = flatten(s':p0) \iff y:s = s'++flatten(p0)) \]

The reducts have been simplified.

Applying the axiom resp. theorem
\[ s++flatten(p) = flatten(s:p) \]

at position \([0,1,1]\) of the preceding formula leads to
True

Example 2 (continued; see section 3) An Expander2 proof by coinduction is presented. The conjecture says that \textit{blink} and \textit{1:blink} contain infinitely many zeros.

\[ \text{fair(eq}(0))(\text{blink}) \& \text{fair(eq}(0))(1:\text{blink}) \]

Applying coinduction w.r.t.
\[ (\text{fair}(f)(s) \iff \text{exists}(f)(s) \& \text{fair}(f)(\text{tail}(s))) \]
at position [] of the preceding formula leads to

$$\exists(eq(0))(1:\text{blink}) \& \text{tail(\text{blink})} = 1:\text{blink} \& \exists(eq(0))(\text{blink}) \vert$$

The reducts have been simplified.

Narrowing the preceding formula (3 steps) leads to

True

**Example 3 (continued; see section 3)** An Expander2 proof by coinduction is presented. The conjecture says that states 3 and 4 satisfy the predicate $X$.

$X(3) \& X(4)$

Applying coinduction w.r.t.

$$(X(st) \implies Y(st))$$

& $$(X(st) \implies OB(b)(X)(st))$$

at position [] of the preceding formula leads to

$$Y(3) \& Y(4) \& OB(b)(X_0)(3) \& OB(b)(X_0)(4)$$

The reducts have been simplified.

Narrowing the preceding formula (25 steps) leads to

True

**Example 4 (continued; see section 3)** An Expander2 proof by coinduction is presented. The conjecture says that updating an array $f$ above index $j$, which represents the top pointer of the stack implemented by $f$, does not change the semantics of $f$ as a stack.

$$i > j \implies (\text{upd}(i,x,f),j) \sim (f,j)$$

Applying coinduction w.r.t.

$$s \sim s' \implies \text{top}(s) = \text{top}(s') \& \text{pop}(s) \sim \text{pop}(s')$$

at position [] of the preceding formula leads to

All $i j x f : (i > j \implies \text{top}(\text{upd}(i,x,f),j) = \text{top}(f,j))$ &
All $i j x f : (i > j \implies$

Any $i0 j0 x0 f0 : (i0 > j0 \& \text{pop}(\text{upd}(i,x,f),j) = (\text{upd}(i0,x0,f0),j0) \& \text{pop}(f,j) = (f0,j0))$

The reducts have been simplified.

Applying the axioms

pop($f,i) = (f,\text{pred}(i))$
& top($f,i) = \text{get}(f,i)$

at positions [1,0,1,0,2,0],[1,0,1,0,1,0],[0,0,1,1],[0,0,1,0] of the preceding formula leads to

All $i j : (i > j \implies i > \text{pred}(j))$ &
All $i j x f : (i > j \implies \text{get}(\text{upd}(i,x,f),j) = \text{get}(f,j))$

The reducts have been simplified.

Applying the axioms

get($\text{upd}(i,x,f),i) = \text{entry}(x)$
& ($\text{get}(\text{upd}(i,x,f),j) = \text{get}(f,j) \iff i /= j$)
at position \([1,0,1,0]\) of the preceding formula leads to
All \(i \ j: (i > j \implies i > \text{pred}(j))\)
The reducts have been simplified.

Applying the theorem
\(i > j \implies i > \text{pred}(j)\)
at position \([0,0]\) of the preceding formula leads to
True

**Example 5 (continued; see section 3)** At first, the logical equivalence between two relational inclusions is proved.

\[
\forall x\ y:((Q \land R) \leq (S \land T)) \iff \forall x\ y:((Q \land S) \leq (T \land C))
\]
Narrowing the preceding formula (7 steps) leads to
\[
\forall x\ y\ z: (Q(x,z) \land R(z,y) \implies S(x,y)) \iff \\
\forall x\ y\ z0: (R(x,y) \land Q(z0,x) \implies S(z0,y))
\]
The reducts have been simplified.

Shifting subformulas at positions \([1,0,0,1],[1,0,1]\) of the preceding formula leads to
\[
\forall x\ y\ z: (Q(x,z) \land R(z,y) \implies S(x,y)) \iff \\
\forall x\ y\ z0: (R(x,y) \land Q(z0,x) \implies S(z0,y))
\]
Simplifying the preceding formula (2 steps) leads to
True

Secondly, the equality of the domains of two relations is derived to a formula that expresses the property that \(R\) is right-unique. Hence the derivation proves that the equality holds true whenever \(R\) is right-unique.

\[
\forall x\ y:((\text{dom}(R \land (R \land C))) \leq \text{dom}(\text{dom}(R \land C)))
\]
Narrowing the preceding formula (33 steps) leads to
\[
\forall x\ z: (R(x,z) \land \forall z0: (R(x,z0) \land z0 \neq z) \implies \\
\forall z1: (\forall z2: (\forall z3: (x \neq z3 \land R(z3,z2)) \land R(x,z2)) \land z2 \neq z1) \land \\
R(x,z1))
\]
The reducts have been simplified.

Substituting \(z\) for \(z1\) at position \([0,0,0,1]\) of the preceding formula leads to
\[
\forall x\ z: (R(x,z) \land \forall z0: (R(x,z0) \land z0 \neq z) \implies \\
\forall z2: (\forall z3: (x \neq z3 \land R(z3,z2)) \land R(x,z2)) \land z2 \neq z)
\]
The reducts have been simplified.

Substituting \(z\) for \(z2\) at position \([0,0,0,1]\) of the preceding formula leads to
\[
\forall x\ z: (R(x,z) \land \forall z0: (R(x,z0) \land z0 \neq z) \implies \\
\forall z3: (x \neq z3 \land R(z3,z)) \land R(x,z)) \land z \neq z)
\]
The reducts have been simplified.

Substituting \(x\) for \(z3\) at position \([0,0,0,0]\) of the preceding formula leads to
\[
\forall x\ z: (R(x,z) \land \forall z0: (R(x,z0) \land z0 \neq z) \implies False)
\]
The reducts have been simplified.
The third derivation is a proof of Newman’s Lemma by Noetherian induction: \( R \) is confluent if \( R \) is well-founded and locally confluent. Local confluence is used in the proof at (*) . The well-foundedness of \( R \) enters the proof in terms of the fact that the induction ordering \( \gg \) is defined as the transitive closure of \( R \) (see Example 5 in section 3).

\[
\text{star}(R)(x,y) \land \text{star}(R)(x,z) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(z,u))
\]

Selecting induction variables at position \([0,0,1]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (star}(R) (!x,y) \land \text{star}(R) (!x,z) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(z,u)))
\]

Applying the axioms

\[
\text{star}(R)(x,x) \\
\land (\text{star}(R)(x,z) \iff R(x,y) \land \text{star}(R)(y,z))
\]

at positions \([0,0,1],[0,0,0]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (Any } y0: (R(!x,y0) \land \text{star}(R)(y0,y)) \land \text{Any } y1: (R(!x,y1) \land \text{star}(R)(y1,z)) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(!x,u))) \\
\land \text{All } R \text{ y y0: (R(!x,y0) \land \text{star}(R)(y0,y) \Rightarrow \text{star}(R)(y,y))} \\
\land \text{All } R \text{ y y0: (R(!x,y0) \land \text{star}(R)(y0,y) \Rightarrow \text{star}(R)(!x,y))} \\
\land \text{All } R : (\text{star}(R)(!x,!x))
\]

The reducts have been simplified.

Substituting \(!x\) for \( u \) at position \([2,0,0,1]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (Any } y0: (R(!x,y0) \land \text{star}(R)(y0,y)) \land \text{Any } y1: (R(!x,y1) \land \text{star}(R)(y1,z)) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(!x,u))) \\
\land \text{All } R : (\text{star}(R)(!x,!x))
\]

The reducts have been simplified.

Substituting \( y \) for \( u \) at position \([1,0,1,0,0,1]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (Any } y0: (R(!x,y0) \land \text{star}(R)(y0,y)) \land \text{Any } y1: (R(!x,y1) \land \text{star}(R)(y1,z)) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(!x,u))) \\
\land \text{All } R : (\text{star}(R)(!x,!x))
\]

The reducts have been simplified.

Applying the axioms

\[
\text{star}(R)(x,x) \\
\land (\text{star}(R)(x,z) \iff R(x,y) \land \text{star}(R)(y,z))
\]

at positions \([3,0],[2,0,1],[1,0,1]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (Any } y0: (R(!x,y0) \land \text{star}(R)(y0,y)) \land \text{Any } y1: (R(!x,y1) \land \text{star}(R)(y1,z)) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(z,u)))
\]

The reducts have been simplified.

Moving up quantifiers at positions \([0,0,0],[0,0,1]\) of the preceding formula leads to

\[
\text{All } R \text{ y z: (Any } y1 y0: (R(!x,y0) \land \text{star}(R)(y0,y) \land R(!x,y1) \land \text{star}(R)(y1,z)) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(z,u)))
\]

Applying the theorem

\[
R(x,y) \land R(x,z) \Rightarrow \text{Any } u: (\text{star}(R)(y,u) \land \text{star}(R)(z,u))
\]
at positions [0,0,0,0], [0,0,0,2] of the preceding formula leads to

\[ \text{All } R \, y \ z \, y_1 \, y_0 : (R(x,y_0) \land R(x,y_1) \land \text{Any } u_0 : (\text{star}(R)(y_0,u_0) \land \text{star}(R)(y_1,u_0)) \land \text{star}(R)(y_0,y) \land \text{star}(R)(y_1,z) \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

The reducts have been simplified.

Moving up quantifiers at position [0,0,2] of the preceding formula leads to

\[ \text{All } R \, y \ z \, y_1 \, y_0 : (\text{Any } u_0 : (R(x,y_0) \land R(x,y_1) \land \text{star}(R)(y_0,u_0) \land \text{star}(R)(y_1,u_0) \land \text{star}(R)(y_0,y) \land \text{star}(R)(y_1,z)) \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

Applying the induction hypothesis

\[ \text{star}(R)(x,y) \land \text{star}(R)(x,z) \implies (!x \implies x \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

at positions [0,0,0,2], [0,0,2,0] of the preceding formula leads to

\[ \text{all } R \, y \ z \, y_1 \, y_0 \, u_0 : (\text{star}(R)(y_0,u_0) \land \text{star}(R)(y_0,y) \land !x \implies y \implies \text{Any } u_1 : (\text{star}(R)(u_0,u_1) \land \text{star}(R)(y,u_1))) \land \text{R}(x,y) \land \text{R}(x,y_1) \land \text{star}(R)(y_1,u_0) \land \text{star}(R)(y_1,z) \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

The reducts have been simplified.

Applying the axioms

\[ (x \implies y \iff R(x,y)) \land (x \implies z \iff R(x,y) \land \text{star}(R)(y,z)) \]

at positions [0,0,5,0], [0,0,2,0] of the preceding formula leads to

\[ \text{all } R \, y \ z \, y_1 \, y_0 \, u_0 : (R(x,y) \land R(x,y_1) \land \text{star}(R)(y_1,u_0) \land \text{star}(R)(y_1,z) \land \text{Any } u_2 : (\text{star}(R)(u_0,u_2) \land \text{star}(R)(z,u_2)) \land \text{star}(R)(y_0,y) \land \text{star}(R)(y_0,u_0) \land \text{star}(R)(y_0,y) \land \text{Any } u_1 : (\text{star}(R)(u_0,u_1) \land \text{star}(R)(y,u_1)) \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

The reducts have been simplified.

Moving up quantifiers at positions [0,0,4], [0,0,7] of the preceding formula leads to

\[ \text{all } R \, y \ z \, y_1 \, y_0 : (\text{Any } u_1 u_2 : (R(x,y) \land R(x,y_1) \land \text{star}(R)(y_1,u_0) \land \text{star}(R)(y_1,z) \land \text{star}(R)(y_1,u_2) \land \text{star}(R)(z,u_2) \land \text{star}(R)(y_0,u_0) \land \text{star}(R)(y_0,y) \land \text{star}(R)(u_0,u_1) \land \text{star}(R)(y,u_1)) \implies \text{Any } u : (\text{star}(R)(y,u) \land \text{star}(R)(z,u))) \]

Applying the induction hypothesis
star(R)(x,y) & star(R)(x,z) ==> (!x >> x ==>) Any u:(star(R)(y,u) & star(R)(z,u))

at positions [0,0,4],[0,0,8] of the preceding formula leads to

All R y z y1 y0 u0 u1 u2:((!x >> u0 ==>
  Any u3:(star(R)(u2,u3) & star(R)(u1,u3)) &
  R(!x,y0) & R(!x,y1) & star(R)(y1,u0) & star(R)(y1,z) &
  star(R)(z,u2) & star(R)(y0,u0) & star(R)(y0,y) &
  star(R)(y,u1) ==>
  Any u:(star(R)(y,u) & star(R)(z,u)))

The reducts have been simplified.

Applying the axioms

(x >> y <= R(x,y))
& (x >> z <= R(x,y) & star(R)(y,z))

at position [0,0,0,0] of the preceding formula leads to

All R y z y1 y0 u0 u1 u2:R(!x,y0) & R(!x,y1) & star(R)(y1,u0) & star(R)(y1,z) &
star(R)(z,u2) & star(R)(y0,u0) & star(R)(y0,y) &
star(R)(y,u1) &
Any u3:(star(R)(u2,u3) & star(R)(u1,u3)) ==>
Any u:(star(R)(y,u) & star(R)(z,u))

The reducts have been simplified.

Moving up quantifiers at position [0,0,8] of the preceding formula leads to

All R y z y1 y0 u0 u1 u2:(Any u3:(R(!x,y0) & R(!x,y1) & star(R)(y1,u0) &
star(R)(y1,z) &
star(R)(z,u2) & star(R)(y0,u0) & star(R)(y0,y) &
star(R)(y,u1) & star(R)(u2,u3) &
star(R)(u1,u3)) ==>
Any u:(star(R)(y,u) & star(R)(z,u))

Applying the theorem

star(R)(x,y) & star(R)(y,z) ==> star(R)(x,z)

at positions [0,0,7],[0,0,9] of the preceding formula leads to

All R y z y1 y0 u0 u2 u3:(star(R)(y,u3) & R(!x,y0) & R(!x,y1) & star(R)(y1,u0) &
star(R)(y1,z) & star(R)(z,u2) & star(R)(y0,u0) &
star(R)(y0,y) & star(R)(u2,u3) ==>
Any u:(star(R)(y,u) & star(R)(z,u))

The reducts have been simplified.

Applying the theorem

star(R)(x,y) & star(R)(y,z) ==> star(R)(x,z)

at positions [0,0,5],[0,0,8] of the preceding formula leads to

True

8 Conclusion

We have given an overview of Expander2 with special focus on the system’s prover capabilities. Other features, such as the generation, editing and combination of pictorial term representations or the use of state terms by the simplifier are described in detail in [22]. Future work on Expander2 and on the underlying Swinging Types approach will concentrate on the following:
Representation of coalgebraic data types in terms of coinductively defined functions and of corresponding subtypes defined in terms of co-Horn clauses for membership predicates or coequalities. First steps towards this extension can be found in [19]. Coalgebraic specifications are also dealt with, e.g., [6, 24, 9, 11]. O’Haskell records [12] may be suitable for embedding standard coalgebraic data types into the simplifier.

Compilers that translate functional or relational programs written in, e.g., Haskell, Maude [10], Prolog or Curry [7] into simplification rules. This might involve the combination of particular programming language constructs and their semantics with the pure algebraic-logic semantics of Expander2 specifications. Related work has been done by combining the algebraic specification language CASL [3] with Haskell [26].

A compiler of UML class diagrams and OCL constraints into Expander2 specifications has been developed in a students’ project. This yields a basis for proving invariants, reachabilities and other safety or liveness properties of object-oriented specifications within Expander2.

Commands for the automatic generation of particular axioms, theorems or simplification rules. Such commands are already available for specifying complement predicates, deriving “generic” lemmas from the least/greatest fixpoint semantics of relations and for turning co-Horn axioms into equivalent Horn axioms (see [22], Axioms menu).

Narrowing and fixpoint (co)induction complement each other with respect to the direction axioms are combined with conjectures: In the first case, axioms are applied to conjectures, and the proof proceeds by transforming the modified conjectures. In the second case, conjectures are applied to axioms and the proof proceeds by transforming the modified axioms. Moreover, narrowing on a predicate \( p \) is, at first, a computation rule, i.e. a rule for evaluating \( p \), while fixpoint induction on \( p \) is a proof rule, i.e. a rule for proving something about \( p \). Strikingly, the situation turns upside down for copredicates: narrowing on a copredicate \( q \) is rather a proof rule, whereas coinduction on \( q \) is used as a computation rule (see 3). This observation makes it worthwhile to look for a uniform proof/computation strategy that uses fixpoint (co)induction already at the medium level of interaction.

The range of applications of Expander2 will be investigated and extended by further case studies. Most specifications designed and proofs and computations performed with the system up to now are listed and classified in the Examples section of the manual [22]. So far, the above-mentioned students’ project for translating UML/OCL specifications into Expander2 has led to the most extensive examples.
